#### Abstract

Nomuraea rileyi (Farlow) Samson is a potential entomopathogenic fungus against lepidopteran pests. This was formulated as wettable powder and oil-based formulations to increase its efficiency in the field by using different carrier materials and oils and these were evaluated in the laboratory against two important noctuid pests, Helicoverpa armigera (Hübner) and Spodoptera litura (Fabricius). Among the wettable powder formulations of N. rileyi, viz., bentonite + glucose (7: 1), talc + glucose (7: 1), bentonite $+\operatorname{sucrose}(7: 1)$ and talc $+\operatorname{sucrose}(7: 1)$ recorded $87.0,74.0,72.0,83.0$ and 75.0 per cent mortality in $S$. litura and $79.0,70.0,66.0$ and 88.0 per cent in $H$. armigera, respectively. The oil-based formulations (tank mix) with pongamia oil, sunflower oil, sesame oil and groundnut oil recorded $74.0,90.0,83.0$ and 87.0 per cent mortality in S. litura and $73.0,89.0,87.0$ and 87.0 per cent in $H$. armigera, respectively.

KEY WORDS: Formulations, Helicoverpa armigera, Nomuraea rileyi, oil-based formulations, Spodoptera litura

## INTRODUCTION

The gram pod borer, Helicoverpa armigera (Hübner) and tobacco leaf eating caterpillar, Spodoptera litura (Fabricius), are cosmopolitan and polyphagous pests. The gram pod borer attacks more than 182 host plants belonging to 47 botanical families in the Indian subcontinent and it is now estimated to feed on more than 200 plant species (Pawar, 1998). Pulse crops are heavily infested by the pest, with total pod damage up to 45 per cent and yield loss up to $60-90$ per cent in India (Anon., 1994). Spodoptera litura is next only to H. armigera in economic importance at national level. Biopesticides used for pest management are environmentally safe, selective, specific in their action and easily biodegradable. They can be used in combination with other control measures in integrated pest management programs.

Apart from viruses and bacteria, fungi also infect insects. The pathogenicity of fungi towards insects has been mainly attributed to various hydrolytic enzymes, such as chitinases, proteases and lipases. Among the entomopathogenic fungi, Nomuraea rileyi (Farlow) Samson seems to be promising because of its widespread occurrence and relative abundance due to its wide host range which
includes all the major caterpillar pests. It is also commonly known that $N$. rileyi induces extensive epizootics in caterpillar pests on groundnut, cabbage, clover, soybean and velvet beans and is a potential candidate for use as a microbial insecticide (Ignoffo, 1981). In India, its epizootics occur in rainy season (Phadke et al., 1978; Lingappa et al., 2000).

The formulation of fungi still awaits a serious effort in formulation technology. Efforts with entomopathogenic fungi tend to be concentrated on conidial formulation (Pereira and Roberts, 1990). In the process of exploring formulations of $N$. rileyi as a cost-effective and ecofriendly tool in the pest management of lepidopteran pests, the present investigation was carried out for the development and evaluation of formulations of $N$. rileyi against $S$. litura and $H$. armigera.

## MATERIALS AND METHODS

The experiments were conducted during 2004-06 in the Department of Agricultural Entomology, at the main campus of the University of Agricultural Sciences, Dharwad. For mass production of $N$. rileyi, the procedure developed by Lingappa and Patil (2002) was followed.

## Development of wettable powder formulations

Dried conidial powder of N. rileyi cultured on broken rice grains $(10 \mathrm{~g})$ was mixed with 90 g of each of fifteen carrier materials (Table 2). Before mixing, these carrier materials were sieved through sieves ( 355 mesh) to maintain uniformity in particle size of conidial powder and the carrier material. These carrier materials were sterilized in an autoclave at $121^{\circ} \mathrm{C}$ and 15 psi for 30 min and mixed with conidial powder and carboxy methyl cellulose was added uniformly to all treatments at $0.1 \%$ by weight.

## Development of oil formulations

One gram of conidial powder of $N$. rileyi obtained from broken rice culture $\left(2.13 \times 10^{9}\right.$ spores $\left.\mathrm{ml}^{-1}\right)$ was mixed with nine ml of autoclaved and cooled oils (listed in Table 1) containing Tween $-80(0.1 \%)$. The conidial load was adjusted to $2.13 \times 10^{8}$ conidia $\mathrm{ml}^{-1}$ by adding the respective oil + Tween 80 mixture.

In vitro evaluation of formulations of N . rileyi on S . litura
Different formulations of N. rileyi were evaluated against third instar larvae. Castor leaves were cut into circular discs of Petri plate $(10 \mathrm{~cm})$ size. The surface area of the leaf disc was calculated. The spray solution was assessed for the number of spores present in one ml . The leaf disc was dipped in the spray fluid. The amount of fluid retained on the disc was measured. The spore load per square centimeter was calculated. The larvae were made to crawl on the leaf disc and feed. The wettable powder based formulations containing $2.13 \times 10^{8}$ conidia $\mathrm{ml}^{-1}$ were assayed against third instar larvae of S. litura. Observations were made from the first day after application for up to ten days. The larval mortality due to $N$. rileyi was expressed in per cent using Abbott's formula.

In vitro evaluation of formulations of N . rileyi on H . armigera
Concentrations of formulations with $10^{8}$ conidia $\mathrm{ml}^{-1}$ were prepared using freshly prepared oil based formulations. Twenty freshly moulted third instar larvae of H. armigera were sprayed to wetness with the help of a hand automizer in a glass Petri plate lined with butter paper and allowed to crawl in the Petri plates for 5 minutes. These larvae were transferred into multicavity trays to avoid cannibalism and provided with soaked bengal gram seeds individually. Daily observations on the mortality of larvae due to $N$. rileyi were made from the first day for ten days after treatment. Per cent larval mortality due to different treatments was computed.

## RESULTS AND DISCUSSION

The data pertaining to per cent mortality of H. armigera due to different treatments of $N$. rileyi are presented in Table 1. Mortality of the third instar larvae commenced on the second day after treatment and it increased with
advancement of days and the exposure period. On the third day after treatment, $N$. rileyi conidia formulated in different oils resulted in 7.8 per cent mortality and reached maximum of 76.4 per cent on the tenth day after treatment, irrespective of formulations. Among formulations, N. rileyi formulated in sunflower oil caused 89.0 per cent mortality ten days after treatment, followed by groundnut oil and sesame oil formulations, with 87.0 per cent mortality, which were on par with each other and also with glycerol. The lowest per cent mortality was recorded in diesel formulation ( $64.0 \%$ ), which was found to be the least effective. It is apparent from the present study and earlier reports that vegetable oils synergize the pathogen, but cannot provide good storability and are detrimental to the conidia. Higher efficacy of oil based formulation might be due to prevention of the desiccation of the conidia which helped in longer survival period and better penetration of peg into the integument (Burges, 1988). These results are in agreement with Nagaraja (2005) who also reported that $N$. rileyi formulated with sunflower oil recorded 93.2 per cent cumulative mortality against $3^{\text {rd }}$ instar larvae of H. armigera.

In the experiment with different carrier materials, bentonite + sucrose ( $7: 1$ ) recorded highest corrected cumulative mortality ( $88.0 \%$ ), followed by talc + sucrose and bentonite formulations (Table 2). The various flourbased formulations recorded the least mortality. Better performance of bentonite + sucrose (7:1) may be due to the adhesive nature of clays which helps in better contact of conidia formulated with clay and sucrose which provide nutrition to the organism. The formulation with gram flour + wheat flour (1:5) might have failed to provide better contact with target site of the insect. The present findings are in conformity with those of Nagaraja (2005) who reported talc based WP formulation caused 87.2 per cent cumulative mortality under laboratory conditions against $H$. armigera.

The mean cumulative mortality due to conidia of $N$. rileyi in oil formulation to S. litura was low for up to 5 days after treatment, ranging from 23.0-36.0\% irrespective of the formulation (Table 3). The highest mortality was recorded in the formulation with sunflower oil $(90.0 \%$ ) ten days after treatment, followed by groundnut oil ( $87.0 \%$ ) and sesame oil ( $83.0 \%$ ). In other formulations, per cent mortality ranged from $64.0-77.0 \%$. The present findings of the investigation are confirm the findings of Nagaraj (2005), who reported that sunflower oil based formulation of $N$. rileyi was superior to other treatments, causing 95.0 per cent mortality of S. litura laboratory condition. Vimaladevi et al. (2002) reported that conidia of N. rileyi + sunflower oil + Triton-x -100 recorded 88.9 per cent mortality on $9^{\text {th }}$ day after exposure under laboratory conditions.

The wettable powder formulations of $N$. rileyi gave low mortality even for up to 7 days after treatment (Table 4). The rate of mortality increased consistently on
Table 1. In vitro evaluation of oil based formulations of $N$. rileyi @ $2.13 \times 10^{8}$ conidia $\mathrm{g}^{-1}$ against $H$. armigera

[^0]increase in exposure period and attained maximum for bentonite + sucrose $87.0 \%$ on the tenth day. The various flour based formulations gave the least mortality. The present findings are in confirmation with the studies of Wiwat (2004), who reported WP formulations of $N$. rileyi with bentonite + sucrose ( $1: 7: 7$ ), bentonite + soil ( $1: 7: 7$ ), bentonite and aluminium silicate were better than fresh conidia in infectivity of mycosis by recording the lowest $\mathrm{LC}_{50}$ values against S. litura. Ramegowda and Nagaraj (2005) also reported the talc-based WP formulation of $N$. rileyi recorded $82 \%$ mortality of S. litura compared to the other formulations tested.

## ACKNOWLEDGEMENT

The authors are thankful to the University of Agricultural Sciences, Dharwad, for providing necessary facilities for the investigations.
