Received 7 January 2003; Revised and accepted 17 May 2003

Abstract

A review of phytoconstituents and biological activities of *Digitalis* species has been presented. Despite the fact that there are about 24 species of this genus spread around the world, the present survey revealed that only 17 species have been studied phytochemically. Hence an attempt is made to present a review on the phytochemical studies of *Digitalis* species which would possibly serve as a source for much potent cardioactive molecules.

Keywords: *Digitalis* species, phytochemical, biological activity.

1. Introduction

The exclusively important genus *Digitalis* (Foxglove Leaves) belong to the family Scrophulariaceae and is distributed through out UK and most parts of the European continent. This genus comprises of 24 species [1]. Interestingly, two species among them, namely *D. purpurea* and *D. lanata* have been cultivated as medicinally important plants through out the world [2].

Although the literature reveals that the physicians at Welsch as early as in the 15th century have used the leaves of *Digitalis* for external application, it was Fuchs in 1542 who

first came up with the name *Digitalis*. It was after the inclusion of *Digitalis* in the London Pharmacopoeia in 1650 that William Withering, a physician and botanist from Birmingham, England, published the clinical importance of *Digitalis* in 1785.

During the late 18th century many researchers like Nativelle (1868), Killani (1891) and Stoll (1938) actively engaged themselves and revealed the chemistry of *Digitalis*. The chemistry of this genus suggested the presence of cardiac glycosides, flavonoids, anthraquinones and also triterpenes. But the most important of the

phytoconstituents contributed by this genus is the striking presence of numerous cardiac glycosides that has proven to be the most important drugs in treating congestive heart failures.

Sir James Mackenzie in 1911 demonstrated for the very first time the actions of *Digitalis* on electrically induced auricular fibrillation [3]. *Digitalis purpurea* popularly known as *Digitalis* is well known for its cardiac glycosides that has even today retained its place as a powerful cardio active drug. The genin (aglycone) containing a five membered lactone ring attached to the steroid nucleus at C-17 is classified as a cardenolide.

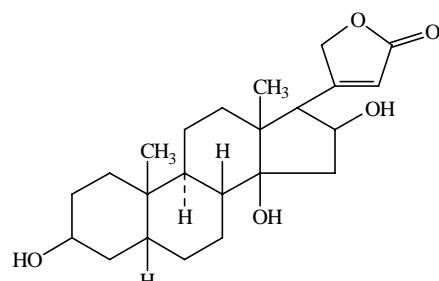

The *Digitalis* species still pose as promising plant members with potential medicinal properties that could be explored extensively. Prompted by these findings and the magnitude at which this genus has gained her place in the therapeutic armamentarium, we felt it worthwhile to present a phytochemical review of all the constituents reported so far from *Digitalis* species along with their sources. This data is prescribed in Table-1.

2. Biological Activity

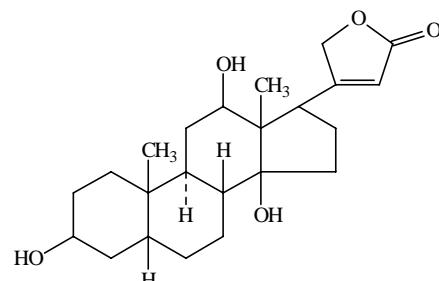

The glycosides of *Digitalis* species are considered to possess cardiac stimulant, wound healing, diuretic and virucidal properties [4, 5]. Many of the *Digitalis* glycosides exhibit slowing ventricular rate in atrial fibrillation, atrial flutter, supraventricular tachycardia and premature extra systoles. Two species of *Digitalis*, *D. purpurea* and *D. lanata* have been reported to possess increasing of coagulability of blood and antagonise the anticoagulant action of heparin in the body [4]. The cardenolides of *Digitalis* increases the force of systolic contractions due to blocking of the Na^+ , K^+ -ATPase pump of the cardiac muscle and increased intracellular $[\text{Na}^+]$, which inturn exchanges with extracellular Ca^{+2} leads to increased intracellular Ca^{+2} levels [6].

Sugars associated with Digitalis glycosides

3. Conclusion

The emergence and use of *Digitalis* species to treat the failing heart has constituted one of the principal life saving drugs of the present century. The cardiac glycosides of *Digitalis* have been hailed as a small group of promising members to treat and prevent coronary and associated circulatory diseases. Taking into account the immense importance of this genus,

the phytoconstituents of the *Digitalis* species have been carefully examined and reported for their allied biological properties.

An overall conclusion on the occurrence and distribution of cardiac glycosides of the genus *Digitalis* highlighted a number of features, primarily the occurrence of the genin, the cardenolide. The cardenolides of *Digitalis*

constitute the five major genins and possess some unique features, which include, the presence of an OH at C-3, a methyl substituent at C-10 and a tertiary OH at C-14. The sugar moieties (glycones) are normally linked to the genin by a C-3, β - linkage to form the cardiac glycosides.

The glycones are composed all together of up to four sugar units which include naturally occurring sugars like glucose or rhamnose, in addition to some rare deoxy-sugars like the 2, 6-di deoxyhexoses (ex: digitoxose), the 3-O-methyl ethers (ex: cymarose, digitalose) and also D-fucose. The sugars namely D-Digitalose, D-Digitoxose, D-fucose, D-Cymarose and D-Glucomethyllose are all of natural occurrence, but seem to be generally confined to the cardiac glycosides of *Digitalis*.

Among the 24 species belonging to this genus, only seventeen have been phytochemically investigated. This suggests that phytochemical work on this genus is by no means futile, as this taxa could still retain some promising new molecules which may be used to treat cardiac ailments in the near future. The wound healing properties of the *Digitalis* members may be attributed to the presence of flavonoid constituents apigenin and luteolin [88].

The cardiac glycosides digoxin, digitoxin, gitoxin and gitaloxin are frequently occurring candidates in the *Digitalis* group and may be considered as taxonomic markers of the genus *Digitalis*. The *Digitalis* species still pose as promising plant members with potential medicinal properties that could be explored extensively.
